Goal

Amani can scale a recipe by multiplying both quantities by the same number, and can explain why adding the difference fails.

Where this sits

Map: Ratios & proportion, Section 3. Prerequisites: equivalent fractions (0.61, being repaired), unit rates (0.86, strong).

Plan (35 minutes)

Min	Step	What happens
0–5	Hook	Her own answer from Monday: 20 chapati → 15 cups. Why did it feel right?
5–12	Counter-example	Two batches: 6 cups, not 11. Let her find the contradiction.
12–20	Model	Ratio table and double number line. Batches, not differences.
20–28	Real context	Grace's order: 300 rolls, 12.5 batches.
28–35	Try and explain	40 chapati. She explains her method aloud.

Success looks like

- Gets 7.5 cups for 20 chapati and explains it as 2.5 batches.
- Rejects "add the difference" and says why.
- Transfers to a new recipe without prompting.

If it isn't landing

- Go hands-on: measure real flour for one batch, then two.
- Return to equivalent fractions: is 2.5 batches the same as 5 half-batches?
- Bring in Nduta for a short check-in before the reassessment.

For parents and guides: praise the reasoning, not just the answer. Ask "how do you know?" more than "is that right?"
